Introduction to Indexing

Outline

Index ? What is it ?

Index versus indexed file organization

Primary (unique) index

Secondary (nonunique) index

Clustered index

B*-tree index implementation

Traversals of B*-tree index

Examples

Index ? What is it ?

An index is a data structure that organizes data records on disk to optimize certain kinds of retrieval operations

An index is used to efficiently retrieve all records that satisfy a search condition on the search key fields of the index

An index is a function $f : K \rightarrow \wp(id_R)$ where K is set of keys and

$\wp(id_R)$ is a powerset (a set of all sets) of identifiers (addresses) id_R of the records in a set R

Let `EMP` be a relational table over a relational schema

```
Employee(enumber, name, department)
```

Then, $F_{department}$domain(department) $\rightarrow \wp(id_{EMP})$ is a function that maps the names of departments in domain(DEPARTMENT) into the sets of identifiers of rows $\wp(id_{EMP})$ in relational table `EMP`

$F_{department}(d)$ returns the identifiers of all rows where a value of attribute `department` is equal to d

Introduction to Indexing

Outline

Index ? What is it ?

Index versus indexed file organization

Primary (unique) index

Secondary (nonunique) index

Clustered index

B*-tree index implementation

Traversals of B*-tree index

Examples

Index versus indexed file organization

An indexed file organization (index organized file) is a function $f : K \rightarrow \wp(R)$ where K is a set of keys and $\wp(R)$ is a powerset (a set of sets) of records R

An index maps a value into set of row identifiers

An index organized file maps a value into a set of records

A relational table can be indexed or it can be index organized

An indexed relational table consists of several index(es) created separately from implementation of a relational table itself

An index organized relational table consists only of implementation of one index where an index key is the same as a relational schema of an index organized table

Indexing in database systems is transparent to data manipulation and data retrieval operations

It means that a database system automatically modifies an index and automatically decides whether an index is used for search

Introduction to Indexing

Outline

Index ? What is it ?

Index versus indexed file organization

Primary (unique) index

Secondary (nonunique) index

Clustered index

B*-tree index implementation

Traversals of B*-tree index

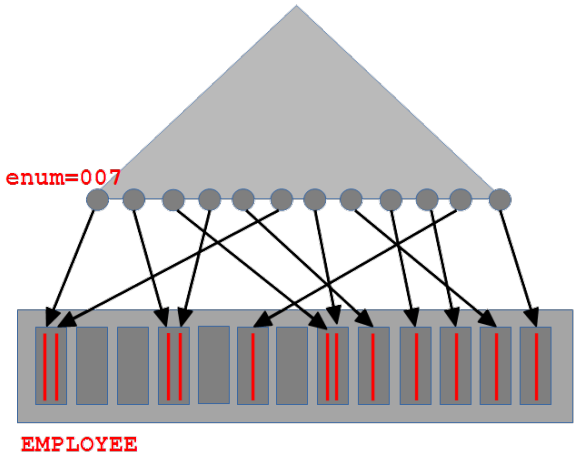
Examples

Primary (unique) index

A primary (unique) index is an index on a set of attributes equal to primary or candidate key

A primary index is a function $f : K \rightarrow id_R$ where K is a set of key values and id_R is a set of identifiers (physical addresses) of rows in a relational table R

A primary index maps and index key into a single row identifier (physical address of a row)



F_{enum}: domain(enum) $\rightarrow id_{EMPLOYEE}$

Primary (unique) index

A primary key in a relational table is always automatically indexed by a database system

For example, a relational table `EMPLOYEE` created over a relational schema `Employee(enum, name, department)` where `enum` is a primary key has an index automatically created on an attribute (`enum`)

For example, a relational table `ENROLMENT` created over a relational schema `Enrolment(snumber,code,edate)` where (`snumber,code)` is a primary key has an index automatically created on a set of attributes (`snumber,code`)

An index on (`snumber,code`) is a composite index

Introduction to Indexing

Outline

Index ? What is it ?

Index versus indexed file organization

Primary (unique) index

Secondary (nonunique) index

Clustered index

B*-tree index implementation

Traversals of B*-tree index

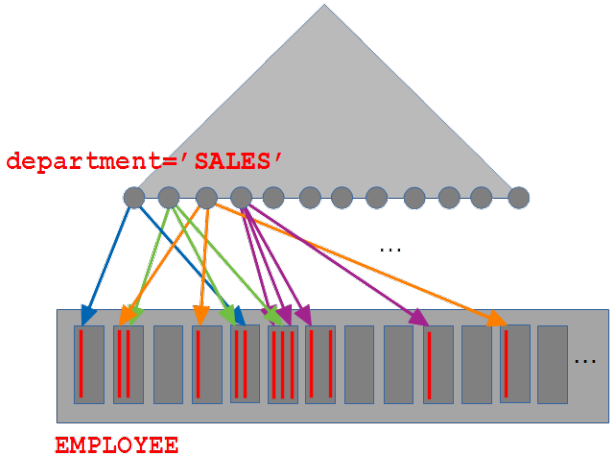
Examples

Secondary (nonunique) index

A secondary index is an index which is not primary

A secondary index is a function $f : K \rightarrow \wp(R)$ where K is a set of key values and id_R is a set of identifiers (physical addresses) of rows in a relational table R

A secondary index maps and index key into a set of row identifiers (a set of physical addresess of the rows)



$F_{department}$: domain(department) $\rightarrow \wp(id_{EMPLOYEE})$

Secondary (nonunique) index

For example, an index on an attrtibute (`name`) in a relational table `EMPLOYEE` created over a relational schema `Employee(enum, name, department)` is a secondary (nonunique) index

For example, an index on a set of attrtibutes (`name, department`) in a relational table `EMPLOYEE` created over a relational schema `Employee(enum, name, department)` is a secondary index

For example, an index on an attribute (`snumber`) in a relational table `ENROLMENT` created over a relational schema `Enrolment(snumber,code,edate)` is a secondary index

An index on a set of attributes (`enum,name`) in a relational table `EMPLOYEE` created over a relational schema `Employee(enum, name, department)` is still a primary index because (`enum,name`) is a superkey

Introduction to Indexing

Outline

Index ? What is it ?

Index versus indexed file organization

Primary (unique) index

Secondary (nonunique) index

Clustered index

B*-tree index implementation

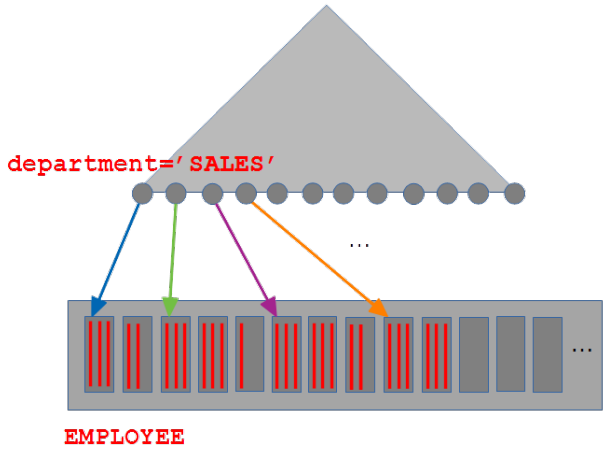
Traversals of B*-tree index

Examples

Clustered index

A clustered index is an index organized such that the ordering of rows is the same as ordering of keys in the index

A clustered index is a function f: K → id_R where K is a set of keys and id_R is a set of row identifiers (addresses) in arelational table R such that f(v) returns row identifier (address) of the first row in a sequence of rows such that a value of atribute K is equal to v



$f_{department}$: domain(department) → $id_{EMPLOYEE}$

Clustered index

Every primary index is clustered

Clustered index provides faster access to data than nonclustered secondary index

Clustered index has a very negative impact on performance of `INSERT` and `UPDATE` SQL statements

Therefore, clustered indexing should be applied to mainly to read-only data

Introduction to Indexing

Outline

Index ? What is it ?

Index versus indexed file organization

Primary (unique) index

Secondary (nonunique) index

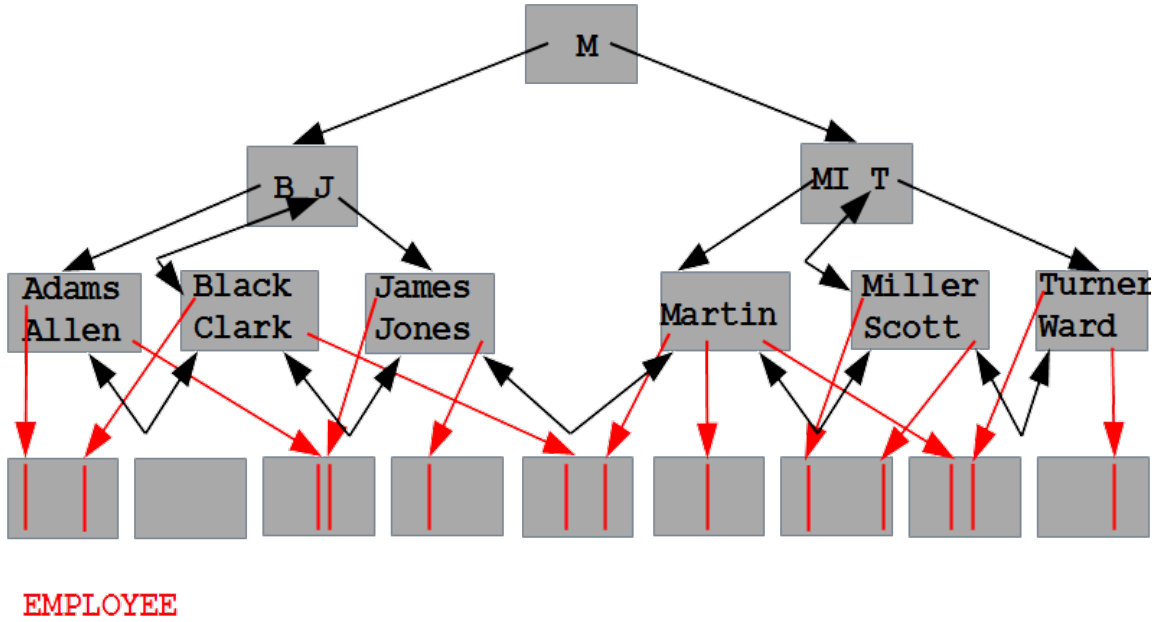
Clustered index

B*-tree index implementation

Traversals of B*-tree index

Examples

B*-tree index implementation



B*-tree can be traversed either:

- vertically from root to leaf level of a tree
- horizontally either from left corner of leaf level to right corner of leaf level or the opposite
- vertically and later on horizontally either towards left lower corner or right lower corner of leaf level

Introduction to Indexing

Outline

Index ? What is it ?

Index versus indexed file organization

Primary (unique) index

Secondary (nonunique) index

Clustered index

B*-tree index implementation

Traversals of B*-tree index

Examples

Traversals of B*-tree index

An index on a primary key (`enum`) in a relational table `EMPLOYEE` created over a relational schema
`Employee(enum, name, department, salary)`
is always built automatically by a database system

A name of an index is the same as a name of primary key constraint in a relational table `EMPLOYEE`

The following queries are processed through a vertical traversal of an index on (`enum`)

```sql
SELECT *
FROM EMPLOYEE
WHERE enum = 007;
```

SQL

```sql
SELECT *
FROM EMPLOYEE
WHERE enum = 007 AND department = 'MI6';
```

SQL

```sql
SELECT enum
FROM EMPLOYEE
WHERE enum = 007;
```

SQL

Traversals of B*-tree index

The following queries are processed through a horizontal traversal of leaf level of an index on (`enum`)

```sql
SELECT COUNT(*)
FROM EMPLOYEE;
```

```sql
SELECT COUNT(enum)
FROM EMPLOYEE;
```

```sql
SELECT COUNT(name)  /* Only if name IS NOT NULL */
FROM EMPLOYEE;
```

```sql
SELECT enum
FROM EMPLOYEE;
```

```sql
SELECT enum, COUNT(*)
FROM EMPLOYEE
GROUP BY enum;
```

```sql
SELECT enum
FROM EMPLOYEE
ORDER BY enum;
```

Traversals of B*-tree index

Assume that we created an index on attribute (`name`) in a relational table `EMPLOYEE` created over a relational schema `Employee(enum, name, department, salary)`

The following queries will be processed through a vertical traversal of an index on (`name`)

```sql
SELECT *
FROM EMPLOYEE
WHERE  name = 'James';
```

SQL

```sql
SELECT *
FROM EMPLOYEE
WHERE name = 'James' and department = 'MI6';
```

SQL

```sql
SELECT count(*)
FROM EMPLOYEE
WHERE name = 'James'
```

SQL

Traversals of B*-tree index

Assume that we created an index on the attributes
`(name, department)`
in a relational table `EMPLOYEE` created over a relational schema
`Employee(enum, name, department, salary)`

The following queries are processed through a vertical traversal of an index on (`name, department`)

```SQL
SELECT *
FROM EMPLOYEE
WHERE name = 'James' and department = 'MI6';
```

```SQL
SELECT count(*)
FROM EMPLOYEE
WHERE name = 'James' and department = 'MI6';
```

```SQL
SELECT *
FROM EMPLOYEE
WHERE name = 'James' and department = 'MI6' and salary > 1000;
```

Traversals of B*-tree index

The following queries can be processed through a vertical traversal and later on horizontal traversal of an index on (`enum`)

```sql
SELECT *
FROM EMPLOYEE
WHERE enum > 300;
```

SQL

```sql
SELECT count(*)
FROM EMPLOYEE
WHERE enum < 007;
```

SQL

```sql
SELECT *
FROM EMPLOYEE
WHERE enum > 300 and salary > 1000;
```

SQL

Traversals of B*-tree index

Assume that we created an index on the attributes
`(name, department)`
in a relational table `EMPLOYEE` created over a relational schema
`Employee(enum, name, department, salary)`

The following queries can be processed through a vertical traversal and later on horizontal traversal of an index on (`name, department`)

```sql
SELECT *
FROM EMPLOYEE
WHERE name > 'James';
```

SQL

```sql
SELECT count(*)
FROM EMPLOYEE
WHERE name <= 'James';
```

SQL

```sql
SELECT *
FROM EMPLOYEE
WHERE name = 'James' and department > 'MI6';
```

SQL

Traversals of B*-tree index

Assume that we created an index on the attributes
`(name, department)`
in a relational table `EMPLOYEE` created over a relational schema
`Employee(enum, name, department, salary)`

The following queries can be processed through a vertical traversal and later on horizontal traversal of an index on (`name, department`)

```sql
SELECT *
FROM EMPLOYEE
WHERE name > 'James' and salary > 1000;
```

SQL

```sql
SELECT name, count(*)
FROM EMPLOYEE
WHERE name > 'James' and salary > 1000
GROUP BY name;
```

SQL

```sql
SELECT *
FROM EMPLOYEE
WHERE name > 'James' and salary > 1000
ORDER BY name;
```

SQL

Traversals of B*-tree index

Assume that we created an index on the attributes
`(name, department)`
in a relational table `EMPLOYEE` created over a relational schema
`Employee(enum, name, department, salary)`

The following queries can be processed through a horizontal traversal of an index on (`name, department`)

```SQL
SELECT *
FROM EMPLOYEE
WHERE department = 'MI6;
```

```SQL
SELECT *
FROM EMPLOYEE
WHERE department > 'MI6;
```

```SQL
SELECT name, department
FROM EMPLOYEE;
```

```SQL
SELECT name, department, count(*)
FROM EMPLOYEE
GROUP BY name, department,
```

Introduction to Indexing

Outline

Index ? What is it ?

Index versus indexed file organization

Primary (unique) index

Secondary (nonunique) index

Clustered index

B*-tree index implementation

Traversals of B*-tree index

Examples

Examples

What index should be created on a relational table `DEPARTMENT` created over a relational schema
`Department(dname, chairperson, budget)`
to speed up the following queries ?

```sql
SELECT *
FROM DEPARTMENT
WHERE dname = 'MI6';
```

There is no need for any new index because an attribute `dname` is a primary key and it is automatically indexed

```sql
SELECT *
FROM DEPARTMENT
WHERE dname = 'MI6' AND  budget > 10000;
```

There is no need for any new index because an attribute `dname` is a primary key and it is automatically indexed

Examples

What index should be created on a relational table `DEPARTMENT` created over a relational schema
`Department(dname, chairperson, budget)`
to speed up the following queries ?

```sql
SELECT *
FROM DEPARTMENT
WHERE budget = 10000;
```

SQL

```sql
CREATE INDEX DEPT_IDX_BUDGET ON DEPARTMENT(budget);
```

SQL

```sql
SELECT *
FROM DEPARTMENT
WHERE budget = 10000 and chairperson = 'James';
```

SQL

```sql
CREATE INDEX DEPT_IDX_BC ON DEPARTMENT(budget,chairperson);
```

SQL

```sql
SELECT DISTINCT chairperson
FROM DEPARTMENT;
```

SQL

```sql
CREATE INDEX DEPT_IDX_CHAIR ON DEPARTMENT(chairperson);
```

SQL

Examples

What index should be created on a relational table `DEPARTMENT` created over a relational schema
`Department(dname, chairperson, budget)`
to speed up the following queries ?

```sql
SELECT *
FROM DEPARTMENT
ORDER BY budget;
```

SQL

```sql
CREATE INDEX DEPT_IDX_BUDGET ON DEPARTMENT(budget);
```

SQL

```sql
SELECT chairperson, budget, count(*)
FROM DEPARTMENT
GROUP BY  budget, chairperson;
```

SQL

```sql
CREATE INDEX DEPT_IDX_BC ON DEPARTMENT(budget,chairperson);
```

SQL

```sql
SELECT chairperson, budget, count(*)
FROM DEPARTMENT
GROUP BY  chairperson, budget;
```

SQL

```sql
CREATE INDEX DEPT_IDX_CB ON DEPARTMENT(chairperson,budget);
```
